Sunat Bhat - knn nosol

January 22, 2022

0.1 This is the k-nearest neighbors workbook for ECE C147/C247 Assignment #2

Please follow the notebook linearly to implement k-nearest neighbors.

Please print out the workbook entirely when completed.

The goal of this workbook is to give you experience with the data, training and evaluating a simple classifier, k-fold cross validation, and as a Python refresher.

0.2 Import the appropriate libraries

```
import numpy as np # for doing most of our calculations
import matplotlib.pyplot as plt# for plotting
from utils.data_utils import load_CIFAR10 # function to load the CIFAR-10_
dataset.

# Load matplotlib images inline

# These are important for reloading any code you write in external .py files.

# see http://stackoverflow.com/questions/1907993/
dautoreload-of-modules-in-ipython

%load_ext autoreload
%autoreload 2
```

The autoreload extension is already loaded. To reload it, use: %reload_ext autoreload

```
[2]: # Set the path to the CIFAR-10 data
cifar10_dir = 'cifar-10-batches-py' # You need to update this line
X_train, y_train, X_test, y_test = load_CIFAR10(cifar10_dir)

# As a sanity check, we print out the size of the training and test data.
print('Training data shape: ', X_train.shape)
print('Training labels shape: ', y_train.shape)
print('Test data shape: ', X_test.shape)
print('Test labels shape: ', y_test.shape)
```

```
Training labels shape: (50000,)
    Test data shape: (10000, 32, 32, 3)
    Test labels shape: (10000,)
[3]: # Visualize some examples from the dataset.
     # We show a few examples of training images from each class.
     classes = ['plane', 'car', 'bird', 'cat', 'deer', 'dog', 'frog', 'horse', _
     ⇔'ship', 'truck']
     num_classes = len(classes)
     samples_per_class = 7
     for y, cls in enumerate(classes):
         idxs = np.flatnonzero(y_train == y)
         idxs = np.random.choice(idxs, samples_per_class, replace=False)
         for i, idx in enumerate(idxs):
            plt_idx = i * num_classes + y + 1
            plt.subplot(samples_per_class, num_classes, plt_idx)
            plt.imshow(X_train[idx].astype('uint8'))
            plt.axis('off')
             if i == 0:
                plt.title(cls)
     plt.show()
```

Training data shape: (50000, 32, 32, 3)

```
[4]: # Subsample the data for more efficient code execution in this exercise num_training = 5000 mask = list(range(num_training))
```

```
X_train = X_train[mask]
y_train = y_train[mask]

num_test = 500
mask = list(range(num_test))
X_test = X_test[mask]
y_test = y_test[mask]

# Reshape the image data into rows
X_train = np.reshape(X_train, (X_train.shape[0], -1))
X_test = np.reshape(X_test, (X_test.shape[0], -1))
print(X_train.shape, X_test.shape)
```

(5000, 3072) (500, 3072)

1 K-nearest neighbors

In the following cells, you will build a KNN classifier and choose hyperparameters via k-fold cross-validation.

```
[5]: # Import the KNN class
from nndl import KNN
```

```
[6]: # Declare an instance of the knn class.
knn = KNN()

# Train the classifier.
# We have implemented the training of the KNN classifier.
# Look at the train function in the KNN class to see what this does.
knn.train(X=X_train, y=y_train)
```

1.1 Questions

- (1) Describe what is going on in the function knn.train().
- (2) What are the pros and cons of this training step?

1.2 Answers

- (1) The KNN training function simply stores the training data into class variables.
- (2) Pros: The training step is simple and fast, as you simply store your entire training dataset. Cons: The training data takes up a lot of space in memory, and classification is slow. We must check distances against every training data point, which is computationally very expensive and slow. The KNN model is hardly a 'model' in the traditional sense since it does not compress or paramterize the training data to increase the speed at which new classifications can be determined. As such, more training data further excaerbates the problem, so scaling to more training data is another issues.

1.3 KNN prediction

In the following sections, you will implement the functions to calculate the distances of test points to training points, and from this information, predict the class of the KNN.

Time to run code: 36.49234914779663 Frobenius norm of L2 distances: 7906696.077040902

Really slow code Note: This probably took a while. This is because we use two for loops. We could increase the speed via vectorization, removing the for loops.

If you implemented this correctly, evaluating np.linalg.norm (dists_L2, 'fro') should return: $\sim\!7906696$

1.3.1 KNN vectorization

The above code took far too long to run. If we wanted to optimize hyperparameters, it would be time-expensive. Thus, we will speed up the code by vectorizing it, removing the for loops.

Time to run code: 0.278778076171875

Difference in L2 distances between your KNN implementations (should be 0): 0.0

Speedup Depending on your computer speed, you should see a 10-100x speed up from vectorization. On our computer, the vectorized form took 0.36 seconds while the naive implementation

took 38.3 seconds.

1.3.2 Implementing the prediction

Now that we have functions to calculate the distances from a test point to given training points, we now implement the function that will predict the test point labels.

0.726

If you implemented this correctly, the error should be: 0.726.

This means that the k-nearest neighbors classifier is right 27.4% of the time, which is not great, considering that chance levels are 10%.

2 Optimizing KNN hyperparameters

In this section, we'll take the KNN classifier that you have constructed and perform cross-validation to choose a best value of k, as well as a best choice of norm.

2.0.1 Create training and validation folds

First, we will create the training and validation folds for use in k-fold cross validation.

```
[10]: # Create the dataset folds for cross-valdiation.
num_folds = 5

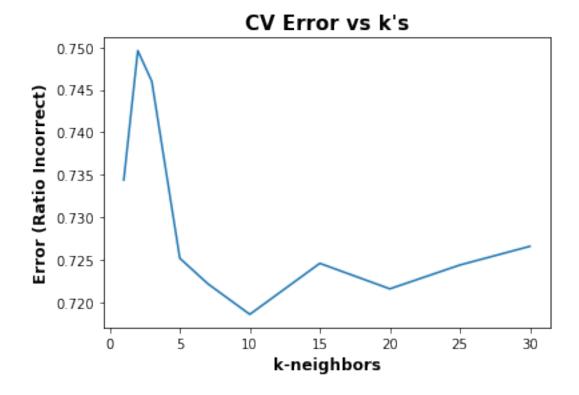

X_train_folds = []
```

2.0.2 Optimizing the number of nearest neighbors hyperparameter.

In this section, we select different numbers of nearest neighbors and assess which one has the lowest k-fold cross validation error.

```
[26]: time_start =time.time()
     ks = [1, 2, 3, 5, 7, 10, 15, 20, 25, 30]
     # ----- #
     # YOUR CODE HERE:
        Calculate the cross-validation error for each k in ks, testing
        the trained model on each of the 5 folds. Average these errors
      together and make a plot of k vs. cross-validation error. Since
        we are assuming L2 distance here, please use the vectorized code!
       Otherwise, you might be waiting a long time.
     errors_k = []
     for i,k in enumerate(ks):
        errors_k.append(0)
        for iFold in range(num_folds):
            X_train_k = np.vstack(X_train_folds[:iFold] + X_train_folds[iFold+1:])
            y_train_k = np.hstack(y_train_folds[:iFold] + y_train_folds[iFold+1:])
           knn.train(X=X_train_k, y=y_train_k)
            dists_L2_vectorized_k = knn.
      →compute_L2_distances_vectorized(X=X_train_folds[iFold])
```

[0.7344, 0.74959999999999, 0.74599999999999, 0.72519999999999, 0.7222, 0.7186, 0.72459999999999, 0.721600000000001, 0.72439999999999, 0.7266] Computation time: 24.26

2.1 Questions:

- (1) What value of k is best amongst the tested k's?
- (2) What is the cross-validation error for this value of k?

2.2 Answers:

- (1) k = 10 has the best performance, or lowest error
- (2) 0.7186 for k = 10 which corresponds to an accuracy of 28.14%

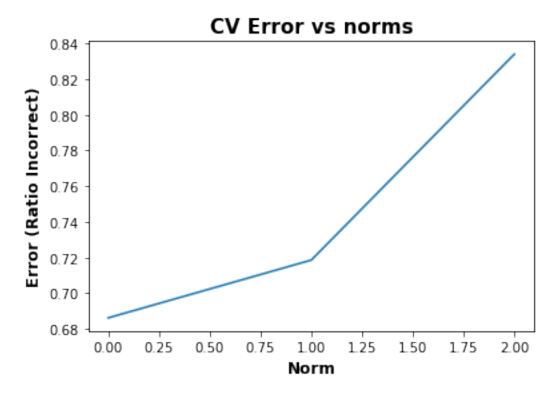

2.2.1 Optimizing the norm

Next, we test three different norms (the 1, 2, and infinity norms) and see which distance metric results in the best cross-validation performance.

```
[18]: time_start =time.time()
     L1_norm = lambda x: np.linalg.norm(x, ord=1)
     L2_norm = lambda x: np.linalg.norm(x, ord=2)
     Linf_norm = lambda x: np.linalg.norm(x, ord= np.inf)
     norms = [L1_norm, L2_norm, Linf_norm]
     # YOUR CODE HERE:
         Calculate the cross-validation error for each norm in norms, testing
         the trained model on each of the 5 folds. Average these errors
         together and make a plot of the norm used vs the cross-validation error
         Use the best cross-validation k from the previous part.
         Feel free to use the compute distances function. We're testing just
      #
         three norms, but be advised that this could still take some time.
         You're welcome to write a vectorized form of the L1- and Linf- norms
         to speed this up, but it is not necessary.
      # ------ #
     errors norm = []
     for i,norm in enumerate(norms):
         errors_norm.append(0)
         for iFold in range(num_folds):
             X_train_k = np.vstack(X_train_folds[:iFold] + X_train_folds[iFold+1:])
             y_train_k = np.hstack(y_train_folds[:iFold] + y_train_folds[iFold+1:])
             knn.train(X=X_train_k, y=y_train_k)
             dists_L2_vectorized_k = knn.
       →compute_distances(X=X_train_folds[iFold],norm=norm)
             y_predict = knn.predict_labels(dists = dists_L2_vectorized_k,k=10)
             errors_norm[i] += (y_predict != y_train_folds[iFold]).sum()/y_predict.
       ⇔shape[0]
```

[0.686200000000001, 0.7186, 0.834]

Computation time: 652.51

2.3 Questions:

- (1) What norm has the best cross-validation error?
- (2) What is the cross-validation error for your given norm and k?

2.4 Answers:

- (1) The L_1 norm
- (2) The CV error is **0.6862** for L_1 norm (with k = 10)

3 Evaluating the model on the testing dataset.

Now, given the optimal k and norm you found in earlier parts, evaluate the testing error of the k-nearest neighbors model.

Error rate achieved: 0.714

3.1 Question:

How much did your error improve by cross-validation over naively choosing k = 1 and using the L2-norm?

3.2 Answer:

The test error rate was reduced from 0.726 to 0.714 for L_1 norm, k = 10, a **decrease of 0.012** (or an increase of 1.2% accuracy).

```
class KNN(object):
 def __init__(self):
   pass
 def train(self, X, y):
   Inputs:

    X is a numpy array of size (num_examples, D)

   y is a numpy array of size (num_examples, )
   self.X_train = X
   self y train = y
 def compute_distances(self, X, norm=None):
   Compute the distance between each test point in X and each training point
   in self.X_train.
   Inputs:
   X: A numpy array of shape (num_test, D) containing test data.
   - norm: the function with which the norm is taken.
   Returns:
   dists: A numpy array of shape (num_test, num_train) where dists[i, j]
     is the Euclidean distance between the ith test point and the jth training
     point.
   1111111
   if norm is None:
     norm = lambda x: np.sqrt(np.sum(x**2))
     \#norm = 2
   num_test = X.shape[0]
   num_train = self.X_train.shape[0]
   dists = np.zeros((num_test, num_train))
   for i in np.arange(num_test):
     for j in np.arange(num_train):
       # YOUR CODE HERE:
         Compute the distance between the ith test point and the jth
         training point using norm(), and store the result in dists[i, j].
      dists[i,j] = norm(self.X_train[j,:] - X[i,:])
      # END YOUR CODE HERE
   return dists
 def compute_L2_distances_vectorized(self, X):
   Compute the distance between each test point in X and each training point
   in self.X_train WITHOUT using any for loops.
   Inputs:
   X: A numpy array of shape (num_test, D) containing test data.
   Returns:
   - dists: A numpy array of shape (num_test, num_train) where dists[i, j]
     is the Euclidean distance between the ith test point and the jth training
     point.
   num_test = X.shape[0]
   num_train = self.X_train.shape[0]
   dists = np.zeros((num_test, num_train))
   # YOUR CODE HERE:
      Compute the L2 distance between the ith test point and the jth
      training point and store the result in dists[i, j]. You may
      NOT use a for loop (or list comprehension). You may only use
      numpy operations.
      HINT: use broadcasting. If you have a shape (N,1) array and
      a shape (M,) array, adding them together produces a shape (N, M)
       array.
         # Compute (A-B)^2
   # For memory efficiency: Compute sqrt( X^2 + X_train^2 - 2*X*X_train')
   # Need to use broadcasting to get all columns element
   # Source: https://stackoverflow.com/a/35814006
   X_{sq\_sum} = np.sum(np.square(X), axis=1).reshape(X.shape[0],1) # X^2 + add axis for broadcasting
   X_train_sq_sum = np.sum(np.square(self.X_train),axis=1)
                                                          # X train^2
   X_dot_X_train = np.dot(X,self.X_train.T)
                                                          # X*X train'
   dists = np.sqrt(X_sq_sum + X_train_sq_sum - 2 * X_dot_X_train) # Compute sqrt( X^2 + X_train^2 - 2*X*X_train')
   # END YOUR CODE HERE
   return dists
 def predict_labels(self, dists, k=1):
   Given a matrix of distances between test points and training points,
   predict a label for each test point.
   Inputs:
   - dists: A numpy array of shape (num_test, num_train) where dists[i, j]
     gives the distance betwen the ith test point and the jth training point.
   Returns:
   - y: A numpy array of shape (num_test,) containing predicted labels for the
     test data, where y[i] is the predicted label for the test point X[i].
   num_test = dists.shape[0]
   y_pred = np.zeros(num_test)
   for i in np.arange(num_test):
     # A list of length k storing the labels of the k nearest neighbors to
     # the ith test point.
     # closest_y = []
     # YOUR CODE HERE:
        Use the distances to calculate and then store the labels of
        the k-nearest neighbors to the ith test point. The function
        numpy.argsort may be useful.
     #
        After doing this, find the most common label of the k-nearest
        neighbors. Store the predicted label of the ith training example
        as y_pred[i]. Break ties by choosing the smaller label.
     # Sources: https://stackoverflow.com/a/23734295 , https://www.delftstack.com/howto/python/mode-of-list-in-python/
     closest_y_s = self.y_train[dists[i,:].argsort()[:k]].tolist()
     y_pred[i] = (max(set(closest_y_s), key = closest_y_s.count))
        # END YOUR CODE HERE
```

import numpy as np

return y_pred

import pdb

Problem 2: Softmax Gradient

Softmax:
$$\frac{e^{ay_i(x)}}{\sum_{k=1}^{c} e^{ay_k(x)}}$$

$$\frac{e^{ay_i(x)}}{\sum_{k=1}^{c} e^{ay_k(x)}}$$

$$\frac{dy_i(x)=\omega_i \times +b_i}{i-closs (for 2\omega_i)}$$

$$\frac{e^{ay_i(x)}}{\sum_{k=1}^{c} e^{ay_k(x)}}$$

$$\frac{e^{ay_i(x)}}{\sum_{i=1}^{c} closs (for 2\omega_i)}$$

$$\frac{e^{ay_i(x)}}{\sum_{i=1}^{c} closs (for$$

As discussed in class, the softmax_k is the probability x^i is in class k.

$$= \sum_{i=1}^{n} P(y^{i}=k|X^{i}, \theta_{k}) = \text{Softmax}_{k}(x^{i})$$

$$= \sum_{i=1}^{n} \log \left[\frac{e^{a_{i}:(x^{i})}}{\sum_{k=1}^{n} e^{a_{k}:(x^{i})}} \right]$$

$$= \sum_{i=1}^{n} \left[a_{i}:(x^{i}) - \log \sum_{k=1}^{n} e^{a_{k}(x^{i})} \right]$$

$$= \sum_{i=1}^{n} \left[a_{i}:(x^{i}) - \log \sum_{k=1}^{n} e^{a_{k}(x^{i})} \right]$$

$$= \sum_{i=1}^{n} \left[a_{i}:(x^{i}) - \log \sum_{k=1}^{n} e^{a_{k}(x^{i})} \right]$$

$$= \sum_{i=1}^{n} \left[a_{i}:(x^{i}) - \log \sum_{k=1}^{n} e^{a_{k}(x^{i})} \right]$$

$$= \sum_{i=1}^{n} \left[a_{i}:(x^{i}) - \log \sum_{k=1}^{n} e^{a_{k}(x^{i})} \right]$$

$$= \sum_{i=1}^{n} \left[a_{i}:(x^{i}) - \log \sum_{k=1}^{n} e^{a_{k}(x^{i})} \right]$$

Note, convention is to use -L for optimization, but this can also be applied to gradient after calculation. Additionally, the 'arg max' term (arg min for -L) is removed as it corresponds to max likelihood and not the log likelihood equation alone.

$$\nabla \tilde{w}_{i} \lesssim \frac{1}{2} \sum_{i=1}^{m} \sum_{i=1}^{m} \left[\tilde{w}_{y_{i}}^{T} \times - \log \sum_{k=1}^{n} e^{\tilde{w}_{k}^{T}} \times \right]$$

$$\text{Left } \frac{1}{2} \sum_{i=1}^{n} \tilde{w}_{y_{i}}^{T} \times i = \sum_{i=1}^{m} \sum_{k=1}^{n} \sum_{i=1}^{n} \sum_{j=1}^{n} \sum_{i=1}^{n} \sum_{j=1}^{n} \frac{1}{2} \left[\tilde{w}_{i}^{T} \times i \right]$$

$$\text{Right } \frac{1}{2} \sum_{i=1}^{n} \sum_{k=1}^{n} e^{\tilde{w}_{k}^{T}} \times i = \sum_{i=1}^{m} \frac{1}{2} \sum_{i=1}^{n} \frac{1$$

Log-Libelihood Softmark (Ni) Gradient

$$\nabla \tilde{w}_{i} \mathcal{L}^{*} = \sum_{i=1}^{m} x^{i} \left[1(y_{i}=j) - sostmax_{k}(x^{i}) \right] \forall j=1..., c \in \mathbb{R}^{m}$$

$$so. \nabla \tilde{w} \mathcal{L}^{*} = \left[\nabla \tilde{w}_{i} \mathcal{L}_{i}, \nabla \tilde{w}_{i} \mathcal{L}_{i}, \nabla \tilde{w}_{i} \mathcal{L}_{i} \right] \in \mathbb{R}^{m \times c}$$

* Note again for convention in optimization, we would take

• 🗸 🕉 🕹

so the update term would be the negative of the above

Sunay Bhat - softmax_nosol

0.2 Training a softmax classifier.

The following cells will take you through building a softmax classifier. You will implement its loss function, then subsequently train it with gradient descent. Finally, you will choose the learning rate of gradient descent to optimize its classification performance.

```
[3]: from nndl import Softmax
```

Softmax loss

```
[5]: ## Implement the loss function of the softmax using a for loop over
# the number of examples
loss = softmax.loss(X_train, y_train)
```

[6]: print(loss)

2.327760702804874

0.3 Question:

You'll notice the loss returned by the softmax is about 2.3 (if implemented correctly). Why does this make sense?

0.4 Answer:

Without any training, our loss should be equivalent to the **natural log of random chance**. In this case with 10 classes, that is $\ln(10)$ which is ≈ 2.3 .

Softmax gradient

```
[7]: ## Calculate the gradient of the softmax loss in the Softmax class.

# For convenience, we'll write one function that computes the loss

# and gradient together, softmax.loss_and_grad(X, y)

# You may copy and paste your loss code from softmax.loss() here, and then

# use the appropriate intermediate values to calculate the gradient.

loss, grad = softmax.loss_and_grad(X_dev,y_dev)
```

```
# Compare your gradient to a gradient check we wrote.

# You should see relative gradient errors on the order of 1e-07 or less if you_____
implemented the gradient correctly.

softmax.grad_check_sparse(X_dev, y_dev, grad)
```

```
numerical: -0.613715 analytic: -0.613715, relative error: 2.040999e-08 numerical: 1.704663 analytic: 1.704662, relative error: 1.935561e-08 numerical: 2.194071 analytic: 2.194071, relative error: 1.067169e-08 numerical: 2.129312 analytic: 2.129311, relative error: 1.520441e-08 numerical: 0.843848 analytic: 0.843848, relative error: 1.152302e-07 numerical: 1.913921 analytic: 1.913921, relative error: 2.743260e-08 numerical: -1.958870 analytic: -1.958870, relative error: 3.339779e-08 numerical: -0.758563 analytic: -0.758563, relative error: 2.882746e-08 numerical: 0.429284 analytic: 0.429284, relative error: 4.920839e-08 numerical: -1.769676 analytic: -1.769676, relative error: 4.309108e-08
```

0.5 A vectorized version of Softmax

To speed things up, we will vectorize the loss and gradient calculations. This will be helpful for stochastic gradient descent.

```
[8]: import time
```

```
[9]: ## Implement softmax.fast_loss_and grad which calculates the loss and gradient
          WITHOUT using any for loops.
     # Standard loss and gradient
     tic = time.time()
     loss, grad = softmax.loss_and_grad(X_dev, y_dev)
     toc = time.time()
     print('Normal loss / grad_norm: {} / {} computed in {}s'.format(loss, np.linalg.
      →norm(grad, 'fro'), toc - tic))
     tic = time.time()
     loss_vectorized, grad_vectorized = softmax.fast_loss_and_grad(X_dev, y_dev)
     toc = time.time()
     print('Vectorized loss / grad: {} / {} computed in {}s'.format(loss_vectorized,__
      anp.linalg.norm(grad_vectorized, 'fro'), toc - tic))
     # The losses should match but your vectorized implementation should be much
      \hookrightarrow faster.
     print('difference in loss / grad: {} /{} '.format(loss - loss_vectorized, np.
      →linalg.norm(grad - grad_vectorized)))
     # You should notice a speedup with the same output.
```

Normal loss / grad_norm: 2.3124758066980844 / 332.7585134313542 computed in 0.22177624702453613s

```
Vectorized loss / grad: 2.312475806698085 / 332.7585134313541 computed in 0.019501924514770508s difference in loss / grad: -4.440892098500626e-16 /2.1250669706601915e-13
```

0.6 Stochastic gradient descent

We now implement stochastic gradient descent. This uses the same principles of gradient descent we discussed in class, however, it calculates the gradient by only using examples from a subset of the training set (so each gradient calculation is faster).

0.7 Question:

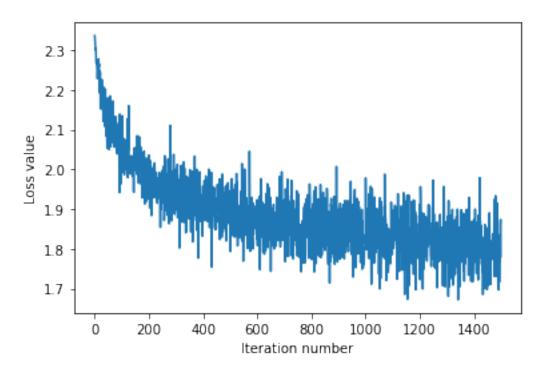

How should the softmax gradient descent training step differ from the sym training step, if at all?

0.8 Answer:

Ignoring as per instructor guidance (Piazza question 125)

```
iteration 0 / 1500: loss 2.3365926606637544
iteration 100 / 1500: loss 2.0557222613850827
iteration 200 / 1500: loss 2.0357745120662813
iteration 300 / 1500: loss 1.9813348165609888
iteration 400 / 1500: loss 1.9583142443981612
iteration 500 / 1500: loss 1.862265307354135
iteration 600 / 1500: loss 1.8532611454359382
iteration 700 / 1500: loss 1.8353062223725827
iteration 800 / 1500: loss 1.829389246882764
iteration 900 / 1500: loss 1.899215853035748
iteration 1000 / 1500: loss 1.9783503540252299
iteration 1200 / 1500: loss 1.8470797913532633
iteration 1200 / 1500: loss 1.8411450268664082
iteration 1300 / 1500: loss 1.7910402495792102
```

iteration 1400 / 1500: loss 1.8705803029382257 That took 7.113604784011841s

0.8.1 Evaluate the performance of the trained softmax classifier on the validation data.

training accuracy: 0.3811428571428571

validation accuracy: 0.398

0.9 Optimize the softmax classifier

You may copy and paste your optimization code from the SVM here.

```
[12]: np.finfo(float).eps
```

[12]: 2.220446049250313e-16

```

learning rate: 0.0001, final loss 24.34482

validation accuracy: 0.29600

The best learning rate by validation accruacy is 1e-06

The validation accruacy for 1e-06is 0.408

0.10 Answer:

Best **tested** learning rate is $1 \times e^{-6}$ with a validation accuracy of 0.408

```
import numpy as np
class Softmax(object):
 def __init__(self, dims=[10, 3073]):
  self.init_weights(dims=dims)
 def init_weights(self, dims):
   Initializes the weight matrix of the Softmax classifier.
   Note that it has shape (C, D) where C is the number of
   classes and D is the feature size.
  self.W = np.random.normal(size=dims) * 0.0001
 def loss(self, X, y):
   Calculates the softmax loss.
   Inputs have dimension D, there are C classes, and we operate on minibatches
   of N examples.
   Inputs:

    X: A numpy array of shape (N, D) containing a minibatch of data.

   - y: A numpy array of shape (N,) containing training labels; y[i] = c means
    that X[i] has label c, where 0 <= c < C.
   Returns a tuple of:
   - loss as single float
   # Initialize the loss to zero.
   loss = 0.0
   # YOUR CODE HERE:
   # Calculate the normalized softmax loss. Store it as the variable loss.
   # (That is, calculate the sum of the losses of all the training
     set margins, and then normalize the loss by the number of
   # training examples.)
